Relative Latency

• Total =
$$A + B + C + D + E$$

• Total = A + B + C + D + E

About IMC

Opportunities @ IMC

- Software Development
- Quantitative Trading

Very heavy CS needs!

http://www.imc.nl/financialmarkets

Some numbers about IMC

- All major worldwide Markets, All Timezones, 6 offices, ~500px
- ~60 datacenters, ~200 links, 10000s equipments
- ~2000 SW deployments

Financial Markets overview

WHAT WE DO IN LESS THAN 2 MIN.

http://www.imc.nl/video/what is market making- 1280x624.mp4

Exchange Price-time priority

- Buyers and Sellers meet at a regulated exchange
- Express their <u>intention</u> to buy / sell
- Orders continuously matched first by price, then time

Imagine this just happened...

	BUYERS			SELLERS		
Chicago	9.98	9.99	10.00	10.01	10.02	10.03
New York	9.96	9.97	9.98	9.99	10.00	10.01

Questions

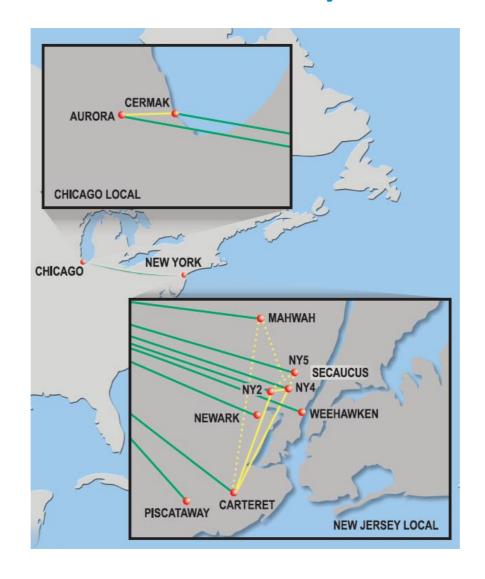

- Q1: what would <u>you</u> do here?
- Q2: what should the <u>market maker</u> do here?

Abstract

We address the problem of how to integrate faulttolerant external and internal clock synchronization. In this paper we propose a new external/internal clock synchronization algorithm which provides both external and internal clock synchronization for as long as a majority of the reference time servers (servers with access to reference time) stay correct. When half or more of the reference time servers are faulty, the algorithm degrades to a fault-tolerant internal clock synchronization algorithm. We prove that at least 2F+1 reference time servers are necessary for achieving external clock synchronization when up to F reference time servers can suffer arbitrary failures, thus the proposed algorithm provides maximum fault-tolerance. In this paper we also derive lower bounds for the best maxiis a granular representation of real-time and is typically provided by a standard source of time such as NIST. Clocks can be externally or internally synchronized [1]. A clock is externally synchronized if at any point in real-time the distance between its value and reference time is bounded by an a priori given constant called maximum external deviation. A set of clocks is internally synchronized if at any point in real-time the distance between the values of two correct clocks in the set is bounded by an a priori given constant called the maximum internal deviation and each clock runs within a linear envelope of real time. Externally synchronized clocks are always internally synchronized by two times the maximum external deviation, but internally synchronized clocks are not always externally

Challenges deploying PTPv2 in a Global Financial company

Pedro V. Estrela IMC Financial Markets, Amsterdam, Netherlands Email: pedro.estrela@imc.nl

Lodewijk Bonebakker IMC Financial Markets, Amsterdam, Netherlands Email: lodewijk.bonebakker@imc.nl

Abstract-This paper describes the challenges encountered when deploying PTPv2 on the worldwide network of a financial company, by upgrading nearly all servers in all data-centers over a period of two years, to achieve global microsecond level accuracy between any pair.

Acknowledging that PTP was initially designed as a LAN protocol and that all current time-keeping industry efforts are focused on PTP, the issues can be broadly divided into a) issues on the PTPv2 standard itself, b) issues that have to be addressed when PTP is expanded to work over WANs, and c) issues that caused the biggest operational impact on the (tested)

In all, this paper contributes concrete examples where PTP's byzantine robustness, scalability and efficiency characteristics range between absent to poor - and attempts to raise awareness on the steps needed to build PTP solutions with the characteristics that global users want.

Using a multi-source NTP watchdog to increase the robustness of PTPv2 in Financial Industry networks

Abstract — This paper describes a fundamental single point of failure in the PTPv2 protocol that affects its robustness to failure in specific error scenarios. The architecture design of electing a single unique time source to a PTP domain - the PTP GrandMaster - makes this protocol vulnerable to byzantine failures.

Previous work has described this vulnerability from both a theoretical and practical point of view - and in particular how this affects the financial industry. This paper advances the discussion by contributing a description of the latest high-accuracy regulatory requirements on the financial industry, and by documenting new examples of failures in real-world customer-facing operations. It then describes an example of one of possible ways to increase PTP robustness while preserving its accuracy (using a multi-source NTP watchdog), and a laboratory test that shows how different protocol implementations are affected by this problem.

In all, the current paper attempts to raise awareness of the robustness requirements within the financial industry today. As only PTP is accurate enough for both current and upcoming regulatory requirements, we hope that these issues are addressed in the

fundamental single point of failure that renders this protocol vulnerable to "byzantine failures" - the worst possible class of failures where failing GMs do not shutdown, but instead start to send misleading time information to their slaves.

Previous work has described this exact vulnerability from both a theoretical [2] and practical point of view [3] - and in particular how this affects the financial industry [4].

To advance the discussion, this paper makes the following

- · a description of the latest regulatory requirements that are pushing higher accuracy obligations to the financial industry ([1] / [13] / [15])
- · a description of new examples of failures in real-world customer-facing operations [10]
- an example of one of the possible ways to increase PTP robustness while preserving its accuracy (using a multisource NTP watchdog to prevent failure scenarios)

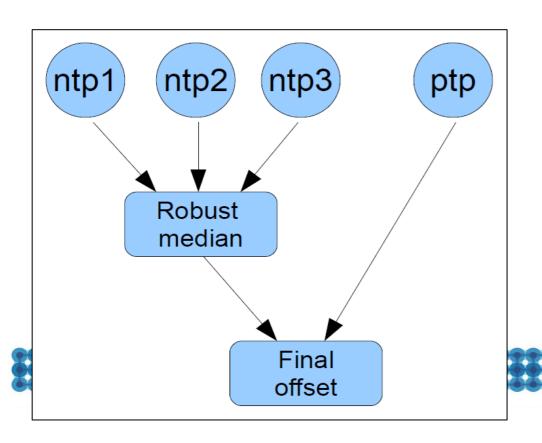

Solution, using with NTP watchdog

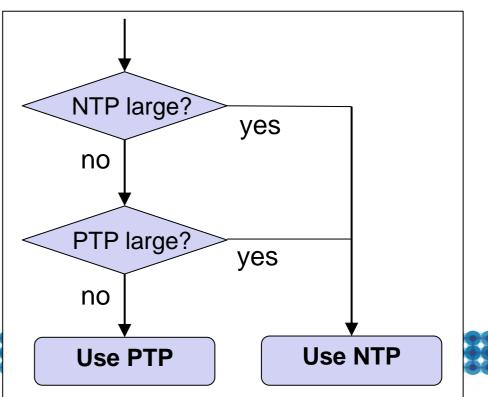

- NTP servers queried in parallel to PTP
- Robust median offset can override PTP offset:
 - -0.2 ms
 - +0.1 ms

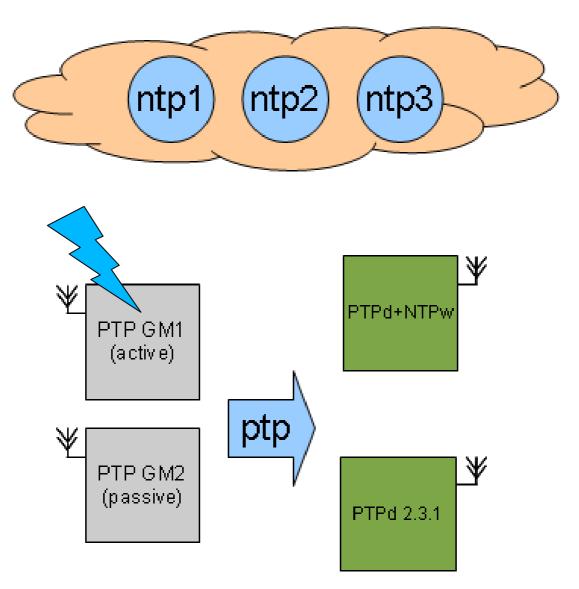

- +35000 ms
- PTP only touches the clock if allowed by the NTP watchdog

Experimental testbed

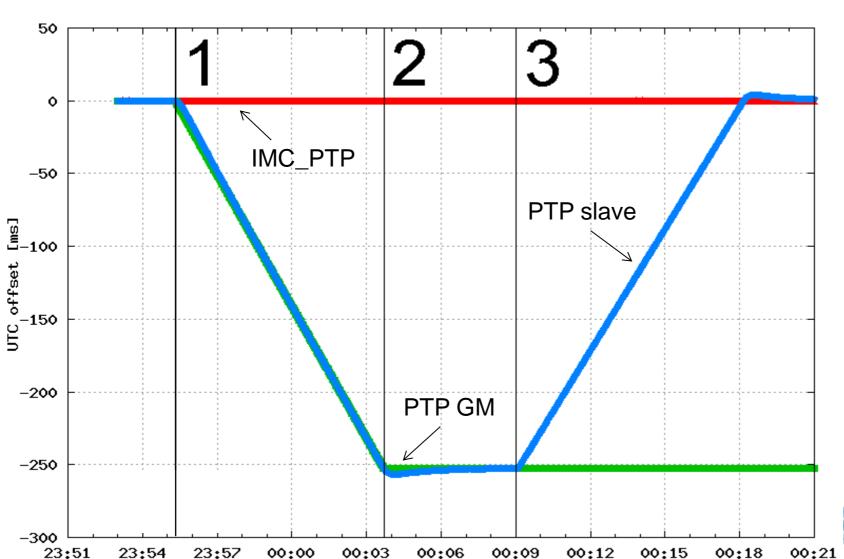

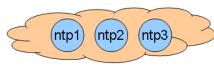

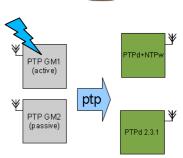

Experimental results

Imc financial markets

- 1 Active GM is slowed-down until 250ms UTC error
- 2 Active GM returns to nominal frequency
- 3 Active GM is killed

Conclusion

IMC opportunities

- Both Software Development and Quantitative Trading
- Both Internships and Full time opportunities
- Research collaborations

Solution 1: no "0" leap seconds

- Leap seconds != "0"
 - Earth has been slowing-down, so we've been <u>adding</u> leap seconds
 - Banning (UTC valid = "1" / UTC offset = "0") would avoid <u>some</u> of the problems for hundreds, if not thousands, of years

Solution 2: Fixed Leap seconds

- Political decision
 - Recognize that "Daylight Saving Time" is a political decision
- Leap seconds = "35" forever
 - On the World RadioCommunications Conference 2015 (WRC-15), fix leap seconds to "35" forever
 - (decision based on ITU studies happening now)
- No Leap hour every 600 years
 - Idea: periodically, skip Daylight Savings Time for a year
 - http://old.post-gazette.com/pg/05210/545823.stm
 - http://leapsecond.com/

Solution 3: Rockets ©

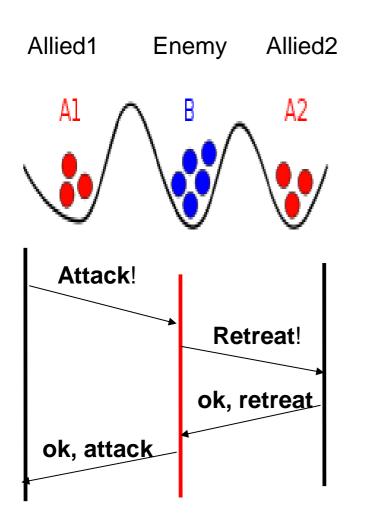

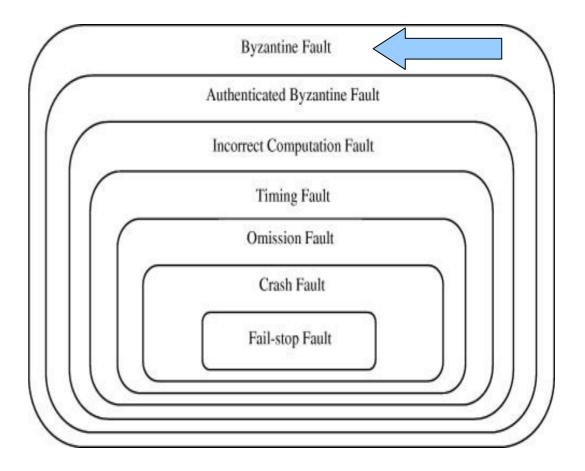

Use rockets to control Earth's rotation

- Either speed up, or speed down
- We can even use a typical PTP "PI" servo
- Could be an easier solution than the other two ©
